TITLE: Nitriding of 25Kh5MA steel

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 4, 1965, 53-55

TOPIC TAGS: steel nitriding, steel hardness, nitriding catalyst, ammonium chloride, aniline / 25Kh5MA steel

ABSTRACT: A study of the change in layer depth and hardness was made under various conditions of nitriding 25Kh5MA steel. In a one-stage nitriding process, after a holding time of 15-16 hrs., the depth of the layer with a hardness of HV 820 does not increase and remains at 0.12-0.14 mm. As the holding time is increased, the layer with hardness HV = 550-300 grows to a slight extent, and after 16 hrs. the process slows down so much that further nitriding is useless. As the temperature is raised from 500 to 560°C (for a 16-hr. holding time), the layer increases by about 0.1 mm, and the hardness decreases from HV 920 to HV 740. In a two-step nitriding process (first stage, 16 hrs. at 500°C; second stage, 5, 10, 15 hrs. at 560°C), the maximum hardness of the nitrided layer HV ≥ 820 was observed

Card 1/2

L 56051-65

ACCESSION NR: AP5010558

at a depth of 0.10-0.15 mm. Ammonium chloride and aniline were tested as catalysts for the acceleration of the nitriding process. With NH₄Cl, no appreciable increase in layer depth was obtained. Aniline increased the depth by 0.05-0.08 mm, but the depth of the very hard layer (HV 820, up to 0.15 mm) remained unaffected. Orig. art. has: 2 figures and 2 tables.

TITLE: Generator of bell-shaped electrical pulses

SOURCE: Pribory i tekhnika eksperimenta, no. 4, 1964, 98-101

TOPIC TAGS: pulse generator, bell shaped pulse generator, variable duration pulse generator

ABSTRACT: A new pulse generator which produces bell-shaped pulses of 20-1,500-microsec duration at a repetition rate of 0.1-1,000 cps is described. The pulse shaping is based on a utilization of the nonlinear characteristics of electron tubes and is performed in two steps: (1) A parabolic-shape pulse corresponding to $U_1(t) = A_1 - a_1 t^2$ is generated in a special stage; (2) This pulse is applied to an exponential-amplitude-characteristic stage described by $k(U) = A_2 e^{a_2 U}$. As a result, a bell-shaped voltage $U(t) = A_2 e^{a_2 (A_1 - a_1 t^2)} = A_2 e^{a_2 A_1} e^{-a_2 a_1 t^2} = A e^{-a_2 a_1 t^2}$

Cord 1/2

L 21717-65

is formed at the output. Some details of the electronic circuit are supplied. The possibility of obtaining bell-shaped r-f pulses (by means of an additional unit) with frequencies 0.1-25 Mc is seen. Orig. art. has: 5 figures and 6 formulas.

TITLE: Ionic-and-Electronic Drive of Metal-Cutting Machines
(Ionno-elektronnyy privod metallorezhushchikh stankov)

PERIODICAL: V sb. Avtomatizatsiya tekhnologicheskikh protsessov v
mashinostroyenii. Privod i upravleniye (Collection: Automation of
Technological Processes in Machine Construction. Drive and Control of
Machines), Moscow, AS USSR, 1956, pp 7-15

ABSTRACT: An ionic drive combined with an electronic-control system is capable of: providing automatic speed change while the machine is running; continuous speed regulation; or maintaining a constant working speed. Attempts to develop the system with a squirrel-cage motor have not proved successful so far. At present, the principal type of adjustable-speed drive still uses the DC motor. The highest operational characteristics are attained with controlled ionic devices in the armature circuit of the electric motor. The field winding may be supplied either from controlled valves or from an uncontrolled phanotron or

Card 1/3

112-57-7-14525

Ionic-and-Electronic Drive of Metal-Cutting Machines

from selenium rectifiers. A comparison is made between a grid-controlled ionic drive and a G-D system. It is pointed out that the generalized power factor -- the ratio of useful power to the apparent power consumed by the drive -- is higher with higher ionic-drive speeds. In machine-tool construction low-power ionic drives of a few kilowatts are used; usually, they include thyratrons. In the ELIR-type thyratron drives developed by ENIMS with capacities of 0.25-3 kw, rigid mechanical characteristics are obtained by means of current and voltage feedbacks, without resorting to a tachometer generator. The motor speed-regulation range varies from 8:1 (main-drive mechanism) to 120:1 (tool-feed mechanisms). The ELIR drive can easily be mounted in the machine-tool or in its control cabinet. The capacity of the ELIR drive is limited by the capacity of thyratrons available so far. Ionic drive can also be adequately used with medium-capacity machines. For such machines, ENIMS has developed an experimental drive with ignitrons up to 30 kw. Regulation of the rectified voltage and motor speed is performed by an electronic device that controls the firing of thyatrons connected in the igniter circuits of the ignitrons. Rigid mechanical

Card 2/3

112-57-7-14525

Ionic-and-Electronic Drive of Metal-Cutting Machines

drive characteristics are obtained by means of a speed feedback accomplished by a tachometer generator. With motor torque changing from 0.2 Mrat to 1.25 Mrat, the motor speed changes about its mean value by $\pm 2\%$ at $n_m = n_{rat}$ to $0.1 n_{rat}$; or by $\pm 4\%$ at $n_m = 0.1$ to $0.04 n_{rat}$; or by $\pm 8\%$ at $n_m = 0.04 n_{rat}$ to $0.02 n_{rat}$ (m - mean, rat - rated). The system secures starting and reversing the motor with an automatic torque limitation. So far, the ELIR drives have inadequate reliability, basically due to the poor quality of thyatrons and phanotrons.

TITLE: The equipment and technological lubrication for the hot rolling of tubes of
AMg6 aluminum-magnesium alloy

SOURCE: Tsvetnyye metally no. 12, 1965, 74-76

TOPIC TAGS: aluminum base alloy, magnesium alloy, hot rolling, metal tube, lubricant
/ AMg6 Al-Mg alloy

ABSTRACT: Since the alloy AMg6 displays highest plastic properties in the temperature range 120-220°C, the rolling of tubes from this alloy is best performed on maintaining these temperatures over the area of deformation. In this connection the authors describe a method of stabilizing rolling technology by preheating the skelp to 100-150°C in an induction heater mounted directly on the KhPT type tube mill. The low-frequency induction-heating installation, operating on industrial-frequency current, consists of an inductor, a 300-kva stepdown transformer, a capacitor battery, a start-up panel, and busbars. The inductor itself (Fig. 1) represents a solenoid coil wound in two layers of rectangular copper tube 14x14 directly on circular stainless-steel liner 1. Insulation 2 of the 23 turns of the coil is of herringbone tape impregnated

with bakelite varnish. To reduce magnetic leakage, four magnetic circuits are installed over the outside diameter of the inductor. The magnetic circuits and inductor winding 4 are insulated against lubricant contamination by housing 5 made of stainless sheet steel. The inductor is affixed to the bed of the rolling mill by means of plate 6. During rolling the friction of skelp at joints leads to the continual formation of metal chips which, unless promptly washed away by the lubricant, may enter the zone of deformation and adhere to the tools, thus causing imprints on the tubes. In this particular case the lubricant must be preheated to 60-80°C before applying it to the deformation zone. The authors tested a large number of the lubricants most suitable for operation in the temperature range 100-200°C. Unfortunately, so far not one has completely met the requirements, since at these temperatures heavy cylinder oils decompose and smoke and, moreover, are difficult to remove from the inside and outside tube surfaces. As for the spindle oil used for the cold rolling of tubes in tube mills, if applied in cold state it causes the cooling of the preheated skelp and hence the cracking of the tubes. The industrial introduction of the warm rolling of tubes of high-strength Al-Mg alloys has resulted in increasing by 30-40% the productivity of KhPT tube mills as well as in increasing by 5-7% the proportion of defect-free tubes. Orig. art. has: 2 figures.

TITLE:

The Kinetics of the Valence Changes of Manganese Stearate in
the Course of the Initial Macroscopic Stage of the Catalytic
Oxidation of n-Decane (Kinetika valentnykh prevrashcheniy
stearata margantsa v khode nachal'noy makroskopicheskoy stadii
katalizirovannogo okisleniya n-dekana)

PERIODICAL:

Zhurnal fizicheskoy khimii, 1959, Vol 33, Nr 1, p. 11-15
(USSR)

ABSTRACT:

A short time ago it was found (refs 1-3) that on the oxidation of n-decane (I) several changes take place in the laurates and stearates of manganese and cobalt. A valence change of the catalyst takes place which causes its falling out and becoming ineffective (Ref 4). In the case under discussion the kinetics of the accumulation of colored intermediate products of these catalysts are investigated. The oxidation of (I) took place in a way already described. The samples were examined in the wave length of 400 m μ by the spectrophotometer S-4. It is stated that the effective activation energy of the accumulation of the intermediate products of manganese stearate is 0.1 kcal on the

Card 1/2

The Kinetics of the Valence Changes of Manganese Stearate in the Course of the Initial Macroscopic Stage of the Catalytic Oxidation of n-Decane

Sov.76-3'-1-36,4.

oxidation of (I), whereas the activation energy of the further reduction of the intermediate compound is 16.1 kcal. The absorption coefficients of the intermediate compound were determined in cumene (since it is simpler than in (I)) and at 400 m μ the value 780 l/g-mol cm was found. Beer's (ber) law is followed up to a catalyst concentration of 0.016 mol (Fig 7). Tests with (I) tetralin, and cumene showed that the absorption coefficient of the intermediate compound obviously does not depend too much on the hydrocarbon to be oxidized (Fig 6). The kinetic curves of the accumulation of colored intermediate products show an initial acceleration (Fig 7). At the curve maximum cumene and tetralin show a complete transition of manganese stearate to a higher valence stage and (I) a 50% transition only. There are 8 figures and 4 Soviet references

TITLE: Exchange of charge between ions on complex molecules

PERIODICAL: Kinetika i kataliz, v. 2, no. 1, 1961, 21-37

TEXT: Processes within the energy range 10^{-1} to $10^1 - 10^2$ ev involve two elementary processes: (I) exchange of heavy particles and molecular regrouping, and (II) exchange of charge which may be accompanied by dissociation. Process (II) which may occur in the case of comparatively slow ions has been little investigated as yet. The present work was undertaken with a view to clarifying this process on complex systems and establishing the extent of competitive occurrence of (I) and (II). It studies the exchange of charge between monoatomic and polyatomic ions in the energy range 10-500 ev. The mass spectrometer used is shown in Fig. 1. Primary ions produced in the ion source 1 by ionizing gas with 60-ev electrons were accelerated to 110-500 ev and separated according to mass in the magnetic analyzer I (angle of deflection 60° , $r = 15$ mm). Ions of specific mass were passed through the collector slit 0.5×2 mm.

into the charge exchange chamber 3. The secondary ions formed in it were deflected at right angles to the beam of primary ions by a weak magnetic field extending into the chamber, accelerated to 15.0-20.0 v, and separated in the magnetic analyzer II (60° , $r = 200$ mm). In chamber 3, ionization could also be excited by electrons emitted from cathode 4. The vacuum in the charge exchange chamber was 10^{-6} - 10^{-7} mm Hg. The primary ion current was 10^{-8} - 10^{-7} a, measured by an electrometer amplifier (a). 5 is an electron multiplier tube, 6 are the deflecting electrodes. Charge exchange was measured on CH_4^+ , C_2H_6^+ , C_3H_8^+ , C_2H_4^+ , C_3H_6^+ , CH_3^+ , NH_3^+ , and N_2H_4^+ . As primary ions the authors used (1), NH_3^+ , NO^+ , CH_4^+ , CH_3^+ , CCl_3^+ , Xe^+ , Zn^+ , Hg^+ (for which the recombination energy was lower than the ionization potential of the molecule), and (2), H_2^+ , Ar^+ , N_2^+ , H_2^+ , H_3^+ (possessing high recombination energies). The experimental data are listed in Tables 1-5. The first columns of these tables indicate the values of m/e in atomic mass units, the potentials

Card 2/15

Exchange of charge between ions ...

at which ions of that mass occur being given in parentheses. The next two columns give the mass spectra as obtained by ionizing the respective molecules with 60-ev electrons. The following columns indicate the mass spectra as obtained by exchange of charge with the ions listed in the first line. The recombination energies are given below the symbols of the primary ions. The amperage I of the secondary ions is given relative to the sum of amperages of all ions produced. The thermal effects of ion formation also appear in the tables. The last line refers to the relative cross section calculated from $\sigma_{\text{rel}} = \sigma/(c_{A^+} - A) = i_{A^+}(dI/dr)/i(dI_{A^+}/dr_A)$, where i_{A^+} denotes the current of primary A^+ ions, I_{A^+} the current of secondary A^+ ions, i the current of primary ions, r_A the radius of the primary ions on the respective molecule, c_{A^+} the argon pressure, P the pressure of the gas under investigation. The mass spectra were taken with primary ions of energy 300-500 v, and a potential of 200 v applied to the drawing electrode. It was found that in the energy

S, 195, 53, 202, 197, 198
B10¹, Fe¹c

range 10^1 - 10^3 ev the transition of kinetic energy to internal energy by charge exchange becomes easier with increasing complexity of the molecule. The cross sections of the charge exchange processes are, therefore, considerable even close to the threshold of endothermic processes, and must be large for exothermic processes, even at low temperature. Consequently, these processes are of considerable importance in real systems (radiation chemistry, reaction during discharge, . . . formation in flames, processes in the upper layer of the atmosphere . . .). Basing on these results, all ion-molecule interactions may be divided into processes with and without formation of a long-lived intermediate ion. One of the two mechanisms is realized depending on the kinetic energy of the collision. The authors thank A. N. Lyutimova and . . . Bulatova, Technician, for their assistance, G. K. Karachevtsev, student, for cooperating in several experiments, and Academician V. I. Kukhleev for discussions. N. N. Tunitskiy, Ye. L. Frankevich, Yu. . . yilin, and A. M. Bukhteyev are mentioned. TEXT: The authors studied the process of charge transfer from slow ions to polyatomic molecules in many different reactions in order to infer charge transfer cross-sections at thermal energies in endothermic reactions or to deduce the behavior of the cross-sections near the threshold energy for endothermic reactions. The effects were investigated of He^+ , A^+ , Xe^+ , N_2^+ , H^+ , H_2^+ , H_3^+ , NO^+ , NH_3^+ , CH_3^+ , CH_4^+ , CCl_3^+ , Ar^+ , Hg^+ , and other ions on molecules such as CH_4 , C_2H_6 , C_2H_4 , C_3H_8 , C_5H_6 , $(\text{CH}_3)_2\text{CO}$, NH_3 , N_2H_4 , and others.

ers; the energies of the ions ranged from 10 to 1000 ev. A mass double mass spectrometer was used. The authors conclude that, in which the experimental results provide evidence for the occurrence of dissociative charge transfer, the ease of conversion of kinetic and internal energy, the effect of the presence of neutral or excited ions in the final system, and the formation of complex intermediate ions. It is considered that the ease of conversion of kinetic into internal energy and vice versa increases linearly with increasing complexity of the molecule and that, therefore, the charge transfer cross-sections in exothermic reactions become larger at thermal energies. There are 5 figures.

TITLE: Pulse mass-spectrometry for studying elementary processes of recharge of thermal ions on molecules ^B

SOURCE: Kinetika i kataliz, v. 5, no. 3, 1964, 377-387

TOPIC TAGS: mass spectrum, pulse, ionization pulse, expansion pulse, inert gas, heavy gas, hydrocarbon, light hydrocarbon, ionization chamber, resonance, thermal ion recharge, iono-molecular reaction, reference gas, ionization velocity constant, Eyring equation, excited ion, excited Xe ion, radiation chemistry, plasma discharge, ionospheres, ion current intensity

ABSTRACT: This method has been developed to study the above processes and is presented. It was selected to obtain iono-molecular reactions under conditions where the energy of the primary ions approaches that of the thermal energy. The authors modified it to weaken the masking effect of the primary ion spectrum; this is particularly effective when the primary ion is much heavier than the second. It was used for Ar⁺, Kr⁺ and Xe⁺ on the molecules CH₄, C₂H₄ and C₂H₆. The ions

Card 1/3

L 10434-63

ACCESSION NR: AP4041059

formed from light hydrocarbons are able to reach the ionization chamber walls faster than those of the heavy inert gas, resulting in an increase of the ratio of concentration of secondary ions (forming upon recharge of the heavy inert gas ions on the hydrocarbon molecules) to concentration of primary hydrocarbon ions. The ionization pulse was 10 volt/10 microseconds, expansion 150 v/7 microseconds. Equipment for the tests is figured, and formulas for the ionization and expansion periods presented. With the pulse method, the intensity of the ion current in the mass spectrum of the hydrocarbon grew somewhat slower than linearly with increase of the inert gas pressure in the ionization chamber. Reference gas was used for correction of electrostatic effects. It was shown that for the processes under study the velocity constant lies in the range of $10^{-9} - 10^{-8}$ cm³.sec.⁻¹. molecule⁻¹ and that the distribution of intensity in the recharged mass spectra coincides for practical purposes with the distribution observed in the recharge on these molecules of the ions Ar, Kr and Xe with an energy of 300 electron volt (Byring equation for reaction cross section). A discussion of the results led to conclusions on the predominance of the resonance mechanism in these processes. Reactions with participation of excited ions are shown, such as Xe^{+(2P₁)}+CH₄-Xe+CH₄+0.44 ev. The iono-molecular interaction was studied under conditions most characteristic for radiation chemistry, ionosphere, certain types of plasma.

mass spectrometer was used in the study. The ion source consisted of two chambers: primary ions were formed in one, and secondary in the other. Pulsed ionization and extraction methods were used to separate these ions. It was noted that the first process virtually does not take place if the energy of the ions becomes greater than 15-20 ev; this is attributed to a decrease in the lifetime of the intermediate complex ion $[O_2H_2]^+$ since during its formation, a considerable part of the kinetic energy of the ion changes into the excitation energy of this complex. A similar behavior of the cross sections with rising kinetic energy of the ion has also been established for the reactions

TITLE: A device for winding information coils for a permanent transformer memory using resettable ferrite cores. Class 42, No. 170763

SOURCE: Byulleten' izobreteniya i tovarnykh znakov, no. 9, 1965, 94-95

TOPIC TAGS: coil winder, resettable core, ferrite core memory

ABSTRACT: This Author's Certificate introduces a device for winding information coils for a permanent transformer memory using resettable ferrite cores. The mechanism is designed for improving the efficiency of the core winding process, increasing the space factor of the core opening and storage volume and increasing the signal-to-noise ratio (improving the quality and reliability of the winding). The device contains a balanced rotating disc with coil forms mounted along the circumference and movable sectional teflon guides located on the outside edge of the disc beyond the coil forms. The guides are situated parallel to the longitudinal axes of the coil forms to make smooth shaping slots opposite the direct axes of symmetry of

Card 1/3

L 52114-65

the forms. The shaping slots are spaced to equal the technological output of a bundle of information coils from the cores. The device also has signal flags located next to each coil form.

TITLE: Analysis of diode logic converter circuits

SOURCE: Vsesoyuznaya nauchnaya sessiya, posvyashchennaya Dnyu radio. 22d, 1966.
Sektsiya elektronno-vychislitel'noy tekhniki. Doklady. Moscow, 1966, 17-23

TOPIC TAGS: computer circuit, digital decoder, logic circuit

ABSTRACT: Diode matrix decoder circuits whose internal states are uniquely determined by the signal combination at their inputs are analyzed. These include binary to decimal converters and coding and decoding circuits. Greater emphasis is placed on logic converters driven by binary ring counters in which one output is associated with each input combination. Multiple-tree and cascaded stage circuits are compared. In an attempt to find a configuration which uses the minimum number of diodes the author concludes that the greatest advantage to be gained is when a two-group double stage decoder is used. Less optimal in this sense are tree circuits and two-group stage decoders. He also notes that decoders with more than two states become complex and the number of serially connected diodes increases giving rise to additional problems.

AUTHORS: Bolotin, L.I., Markin, P.S., and Meleshkov, S. I.
TITLE: A pulse source of multiply charged ions with magnetic beam separation

PERIODICAL: Pribory i tekhnika eksperimenta, no.6, 1961, 66-80
TEXT: The source is capable of producing multiply charged ions with energies up to 40 kV, focussed into a spot 15 mm in diameter. The beam currents are as follows: 1.4 mA (N^{+4}), 1.5 mA (N^{+3}), 2 mA (N^{+2}). The multiply charged ions are produced in the plasma of a high-power arc discharge. The source is illustrated schematically in Fig. 1a (1 - stainless steel, 2 - porcelain, 3 - titanium). The anode is made of copper and the cathode of titanium. Water cooling is not necessary. The anode is insulated from the cathode by porcelain insulators and the position of the stainless steel extractor can be adjusted without releasing the vacuum. The discharge chamber is placed in a magnetic field of 4000 Oe produced by 100° sector electromagnet with a gap of 10 cm (average radius of ion trajectory 15 cm)

Card 1/3

33148
S/120/61/000/006/016/041
A pulse source of multiply charged... E032/E114

The symmetric disposition of the cathode relative to the anode leads to a longitudinal oscillation of the ionizing electrons which reach their maximum energy at the mid-point of the discharge channel (length 40 mm, diameter 8 mm). The slit through which the ions are extracted (15 x 2 mm) is placed in the latter position. The location of the source in the magnetic field is such that the extracted ions will have travelled through one quadrant when they leave the magnetic field in the 90° focal plane. Thus, ions with equal e/m have parallel trajectories, which facilitates the subsequent formation of the beam. The discharge is excited by 10 kW square pulses. The extraction is achieved by means of 40 kW square pulses. The discharge and extracting pulses are synchronized with the aid of a two-channel delay line. The system is evacuated by two diffusion pumps M-1000 (M-1000) (3×10^{-6} mm Hg in the accelerating tube). There are 3 figures, 1 table and 3 references: 1 Soviet-bloc and 2 non-Soviet-bloc. AUTHORS: Bolotin, L.I., Markin, P.S., Kulygin, Yu F.,
Skoromnyy, G.M., and Meleshkov, S.I.

TITLE: A spark source of multiply charged ions

PERIODICAL: Pribory i tekhnika eksperimenta no.6, 1961. 68 90

TEXT: A.A. Plyutto K.P. Kervalindze and I.F. Kvartskhava (Ref. 2: Atomnaya energiya v.3, no.8, 1957, 153) have described a spark source producing large currents of multiply charged ions of various elements with a total ion current of 1 amp. The aim of the present work was to improve the spark source so that it can be used to obtain large currents of N^{+4} and C^{+4} , suitable for injection into a linear accelerator. The source is illustrated schematically in Fig. 1 and differs from that described in Ref. 2. The spark discharge takes place in the AlN channel, which means that one can use both positive and negative half-periods of the oscillatory circuit supplying the spark and exclude ions of elements present in the porcelain tube. During a high-power discharge, the products of decomposition of AlN

Card 1/1 ✓

33149

A spark source of multiply charged

S/120/51/000/006/017/041
E032/E114

are ionized and set up a pressure in the channel, which ejects the plasma into the solenoid. The discharge current passing through the solenoid produces an axial magnetic field which prevents ion diffusion in the plane perpendicular to the magnetic field. The ions are extracted by a voltage of 15 to 20 kV. The beam is then focussed by an electrostatic lens and is accelerated to 50 keV. The pressure in the system is maintained at 10^{-6} mm Hg. It was found that with a frequency of 10 k /sec the following currents could be produced:

200 μ A (C^{+3}), 300 μ A (C^{+3}), 300 μ A (N^{+3}), 200 μ A (O^{+3}). At $f = 5 \times 10^5 - 10^6$ cps (spark length 10-15 usec) the ions N^{+4} and N^{+5} were found to appear. Fig. 2 shows a typical spectrum obtained with $V_c = 38$ kV, $L = 5 \mu$ H and $C = 0.02 \mu$ F. The ion spectrum obtained from the spark source contains 22 components and 30% of the total current is due to nitrogen ions. The energy spread of the ions is about 2 to 3 keV and depends on the spark discharge potential difference. The performance of the source depends on the number of pulses which it has produced. After 10^6 pulses the total ion current decreases by a factor of 10.

Card 2/8

A spark source of multiply

33149
S/120/61/000/006/017/041
E032/E114

The maximum current which can be obtained with the AlN discharge channel is 15 mA. The source produced 100 μ A of N^{+4} in a pulse of 15 μ sec and 300 to 500 μ A of N^{+3} and C^{+3} in a pulse of 500 μ sec. The power consumed by the source and the ion-optical system is 500 W. The present results differ from those reported in Ref. 2. The difference is ascribed to the fact that the present authors measured the true current (i.e. the current beyond the focusing system and the accelerating tube). There are 4 figures and 5 references: 2 Soviet-bloc and 3 non-Soviet-bloc. The English language references read as follows:

TITLE: The Solution of the Unsteady Heat Conduction Problem for
a Rod With Two Masses Attached to Its Ends. The Calculation
of a Differential Thermobattery

PERIODICAL: Zhurnal tekhnicheskoy fiziki, 1960, Vol. 30, No. 9,
pp. 1128-1133

TEXT: The authors investigated the temperature distribution in a one-dimensional rod, to the ends of which masses are attached which are placed in media whose temperature changes linearly. The problem is formulated in the first part of the paper. The authors write down the linear heat conduction equation, and indicate the boundary conditions. The differential equation system set up here is solved with the aid of a contour integral by means of a meromorphous function which is found when solving the differential equation $aY''(x) - bY(x) - \lambda^2 Y(x) = \varphi(x)$. The solution obtained for the problem studied is used for the calculation of a Chromel-Copel differential battery. The construction of the latter is described with

the aid of Fig. 1. Fig. 2 graphically shows the experimental values obtained for the time dependence of the thermoelectromotive force of a battery with 50 thermocouples at a temperature jump from 20° to 50°C. The theoretical curve calculated with the solution obtained here shows a good agreement. The authors thank Docent M. L. Rasulov for valuable remarks. There are 2 figures and 5 Soviet references.

✓ 4658. STARTING BURNER FOR BOILER FIRED WITH LEAN COAL. Boev, I.F., Litvak, N.R., Markin, S.G. and Polikrov, K. Ya. (Energatik (Prv Engr, Moscow), June 1954, 1-5). An illustrated description is given of auxiliary burners used for starting up and low-load operation of a pulverized fuel boiler. There are two auxiliary pulverized coal burners, each with an oil burner below it, in a small auxiliary combustion chamber with a brick baffle. (L).
